

1. An email phishing attack that led to a ransomware infection. I think this because employees received an email pretending to be from a legitimate source and were directed to a fake login portal. After entering their usernames and passwords, their credentials were stolen.
2. Identify and document the affected users and systems, examine the phishing email and malicious link/file, review relevant logs for indicators of compromise, determine the scope of the incident, preserve evidence, and escalate/report the incident through the organization's incident-response process. If necessary, begin isolating systems that are actively affected.
3. **Contain:** Isolate affected computers from the network, disable compromised employee accounts
Resolve: Identify and remove the malicious software from affected systems, patch or secure any vulnerabilities
Recover: Restore from clean backups, reset credentials, verify clean systems and monitor for suspicious activity.
4. Employee training, Network segregation, MFA, update security controls and procedures
